## Periodic boundary conditions

## Bulk modulus

## Bottom to up

- ▶ Generate microstructures that maximize bulk modulus under specified volume fractions as key microstructures.
- ▶ Obtain microstructures for any  $\rho$  through interpolation.
- ▶ Use these as basic units for macroscopic optimization.

# Microstructure interpolation

- ▶ Constructing smooth deformations between two key shapes.
- ▶ Two differences from traditional shape metamorphosis:
  - ▶ The structures have quite similar features.
  - ▶ More focused on smooth variations of physical properties.

## Hashin-Shtrikman bounds

$$K^{\text{HS}}(\rho) = K_0 - \frac{1 - \rho}{\frac{1}{K_0} - \frac{3\rho}{3K_0 + 4G_0}}, \quad (7)$$

$$G^{\text{HS}}(\rho) = G_0 - \frac{1 - \rho}{\frac{1}{G_0} - \frac{6\rho(K_0 + 2G_0)}{5G_0(3K_0 + 4G_0)}}. \quad (8)$$

## Relationship between $E_{ijkl}$ and $\rho$

- ▶ We have several key microstructures.
- ▶ Through interpolation, we have microstructures for each volume fraction, thus obtaining the corresponding  $E_{ijkl}$ .
- ▶ In practice, we directly fit a curve  $E_{ijkl}(\rho)$  based on the data from key microstructures.

$$E_{ijkl}^{\text{fit}}(\rho) = E_{ijkl}^0 - E_{ijkl}^0 \frac{1 - \rho}{1 + a_{ijkl}\rho}.$$

## Relationship between $E_{ijkl}$ and $\rho$

$$E_{ijkl}^{\text{fit}}(\rho) = E_{ijkl}^0 - E_{ijkl}^0 \frac{1 - \rho}{1 + a_{ijkl}\rho}.$$

- ▶ The functional form is inspired by the H-S bounds.
- ▶  $a_{ijkl}$  is obtained through the least squares method.
- ▶ This formula replaces SIMP in the workflow.
- ▶ Predicts data when  $\rho$  is less than the minimum value or greater than the maximum value.

# Compatibility

## Parameter: CellCount

- ▶ The number of key microstructures.
- ▶ `volfrac = linspace(Vmin,Vmax,CellCount);`
  - ▶ For example, `vlinspace(0.2, 0.6, 3)` yields `[0.2, 0.4, 0.6]`.

## Parameter: IC

IC = 1

IC = 2

IC = 3

Initialization of the  $i$ -th key microstructure

## Homogenization of key microstructure

- ▶ function  $CH = \text{homogenize}(lx, ly, \text{lambda}, \text{mu}, \text{phi}, x)$
- ▶  $lx$  = Unit cell length in x-direction.
- ▶  $ly$  = Unit cell length in y-direction.
- ▶  $\text{lambda}$  = Lamé's first parameter for materials. Two entries.
- ▶  $\text{mu}$  = Lamé's second parameter for materials. Two entries.
- ▶  $\text{phi}$  = Angle between horizontal and vertical cell wall. Degrees
- ▶  $x$  = Material indicator matrix.

## Homogenization of key microstructure

- ▶ `[nely, nelx] = size(x);`
- ▶ `dx = lx/nelx; dy = ly/nely;`
- ▶ `nel = nelx*nely;`

## Combine Bottom to up with Compatibility

- ▶ Use compatibility method when generating key microstructure.
